Business Context

Cedarbridge currently lacks a centralized and standardized process for managing internal IT support requests. Employees submit requests through a shared IT support inbox or directly contact IT support specialists through Microsoft Teams.

Upon receiving a request, IT staff informally assess its urgency and determine whether it can be resolved immediately or requires further investigation. More complex issues may be passed between team members or require additional follow-up with employees. Once an issue is resolved, employees are typically notified through Teams or email, without a consistent formal closure process.

While this approach provides flexibility for resolving straightforward issues, it creates challenges in consistently tracking, managing, and reporting on IT support activities.

1. Fragmented Request Tracking

IT requests are received through multiple communication channels without a consolidated mechanism for recording and managing them. As a result, the IT team lacks a reliable, complete view of active and outstanding requests, increasing the risk of requests being overlooked or duplicated.

2. Inconsistent Ownership and Prioritization

Ticket ownership, assignment, and prioritization are not consistently documented. This creates situations where multiple IT staff may investigate the same issue while other requests remain unattended. The absence of clearly recorded responsibilities limits accountability and makes coordination more difficult.

3. Limited Operational and Management Visibility

Cedarbridge lacks reliable, readily accessible information on outstanding requests, their age, resolution progress, and recurring issues. Obtaining this information currently requires manually reviewing emails, conversations, and notes, limiting the ability of IT management and leadership to evaluate performance, identify bottlenecks, and make informed operational decisions.

4. Insufficient Employee Communication and Transparency

Employees do not have a consistent way to confirm that their requests have been received, monitor their progress, or determine when an issue has been formally resolved. This can result in repeated follow-ups, uncertainty, and reduced confidence in the IT support process.

5. Inconsistent Documentation and Request Closure

The current process does not consistently capture ticket history, changes in responsibility, actions taken, or formal resolution details. This makes it difficult to transfer requests between team members, maintain continuity, and establish a complete record of IT support activities.
